## Abstract

Torsion-Bar Antenna (TOBA) is a ground-based GW detector using a torsion pendulum. The resonant frequency of torsional motion is  $\sim 1$  mHz, therefore TOBA has good design sensitivity in low frequency, specifically  $10^{-19} / \sqrt{\text{Hz}}$  at 0.1 Hz. TOBA can detect intermediate-mass black hole binary mergers, Newtonian noise, and so on. A prototype detector Phase-III TOBA with a 35 cm-scale pendulum is under development to demonstrate noise reduction. The target sensitivity is set to  $10^{-15} / \sqrt{\text{Hz}}$  at 0.1 Hz.

To achieve our target sensitivity, we need to measure the pendulum rotation precisely. We propose a wavefront sensor with a coupled cavity (Coupled WFS) as an angular sensor for Phase-III TOBA. In our method, an auxiliary cavity is used to compensate Gouy phase of a main cavity and enhance the first-order TEM modes in the main cavity. The experimental demonstration was successfully performed in 2021. Here we show the principle and demonstration results of a Coupled WFS.

## 1. Introduction of TOBA

### TOBA: Torsion-Bar Antenna [1]

- Ground-based GW detector for low frequency
- Aim to detect the torsional rotation of test masses suspended horizontally
- The resonant frequency of torsional motion is low ( $\sim 1$  mHz)  $\rightarrow$  Good sensitivity in low frequency even on the ground
- Scientific targets: intermediate-mass black hole binary mergers, Newtonian noise, Earthquake early warning, etc.

### Development plan [2]

Phase-I (2009)	Phase-II (2015)	Phase-III (Now)	Final (Future)
Principle test		Technical demonstration	GW observation
$10^{-8} / \sqrt{\text{Hz}}$ at 0.1 Hz (Established)		$10^{-15} / \sqrt{\text{Hz}}$ at 0.1 Hz (Target)	$10^{-19} / \sqrt{\text{Hz}}$ at 0.1 Hz (Target)
20 cm bars Room temp.		30 cm bars Cryo. Temp. (4 K)	10 m bars Cryo. Temp. (4 K)

$\Rightarrow$  See [Satoru's poster \(#A14\)](#) for more details about TOBA

## 2. Principle of Coupled WFS

### Coupled WFS:

#### Wavefront sensor with a coupled cavity

- An improved WFS proposed to measure the torsional rotation of TOBA test masses accurately
- An auxiliary cavity can compensate Gouy phase of a main cavity  $\rightarrow$  Both TEM<sub>00</sub> and TEM<sub>10</sub> are resonant in the main cavity  $\rightarrow$  Angular signal is amplified by the finesse of the main cavity

### Comparison of angular sensors

	Michelson interferometer	WFS	Coupled WFS
Shot noise (Requirement: $5 \times 10^{-16}$ rad/ $\sqrt{\text{Hz}}$ )	😊	😞 No signal amplification	😊 Signal amplification
Frequency noise	😞 Asymmetry of two light paths	😊	😊
Beam jitter noise	😞 Non-parallel of two mirrors	😞	😊 No amplification of beam jitter
Thermal noise	😊	😞 Narrow range measurement	😞 Narrow range measurement
Linear range	😊	😊	😞 Trade-off with signal amplification

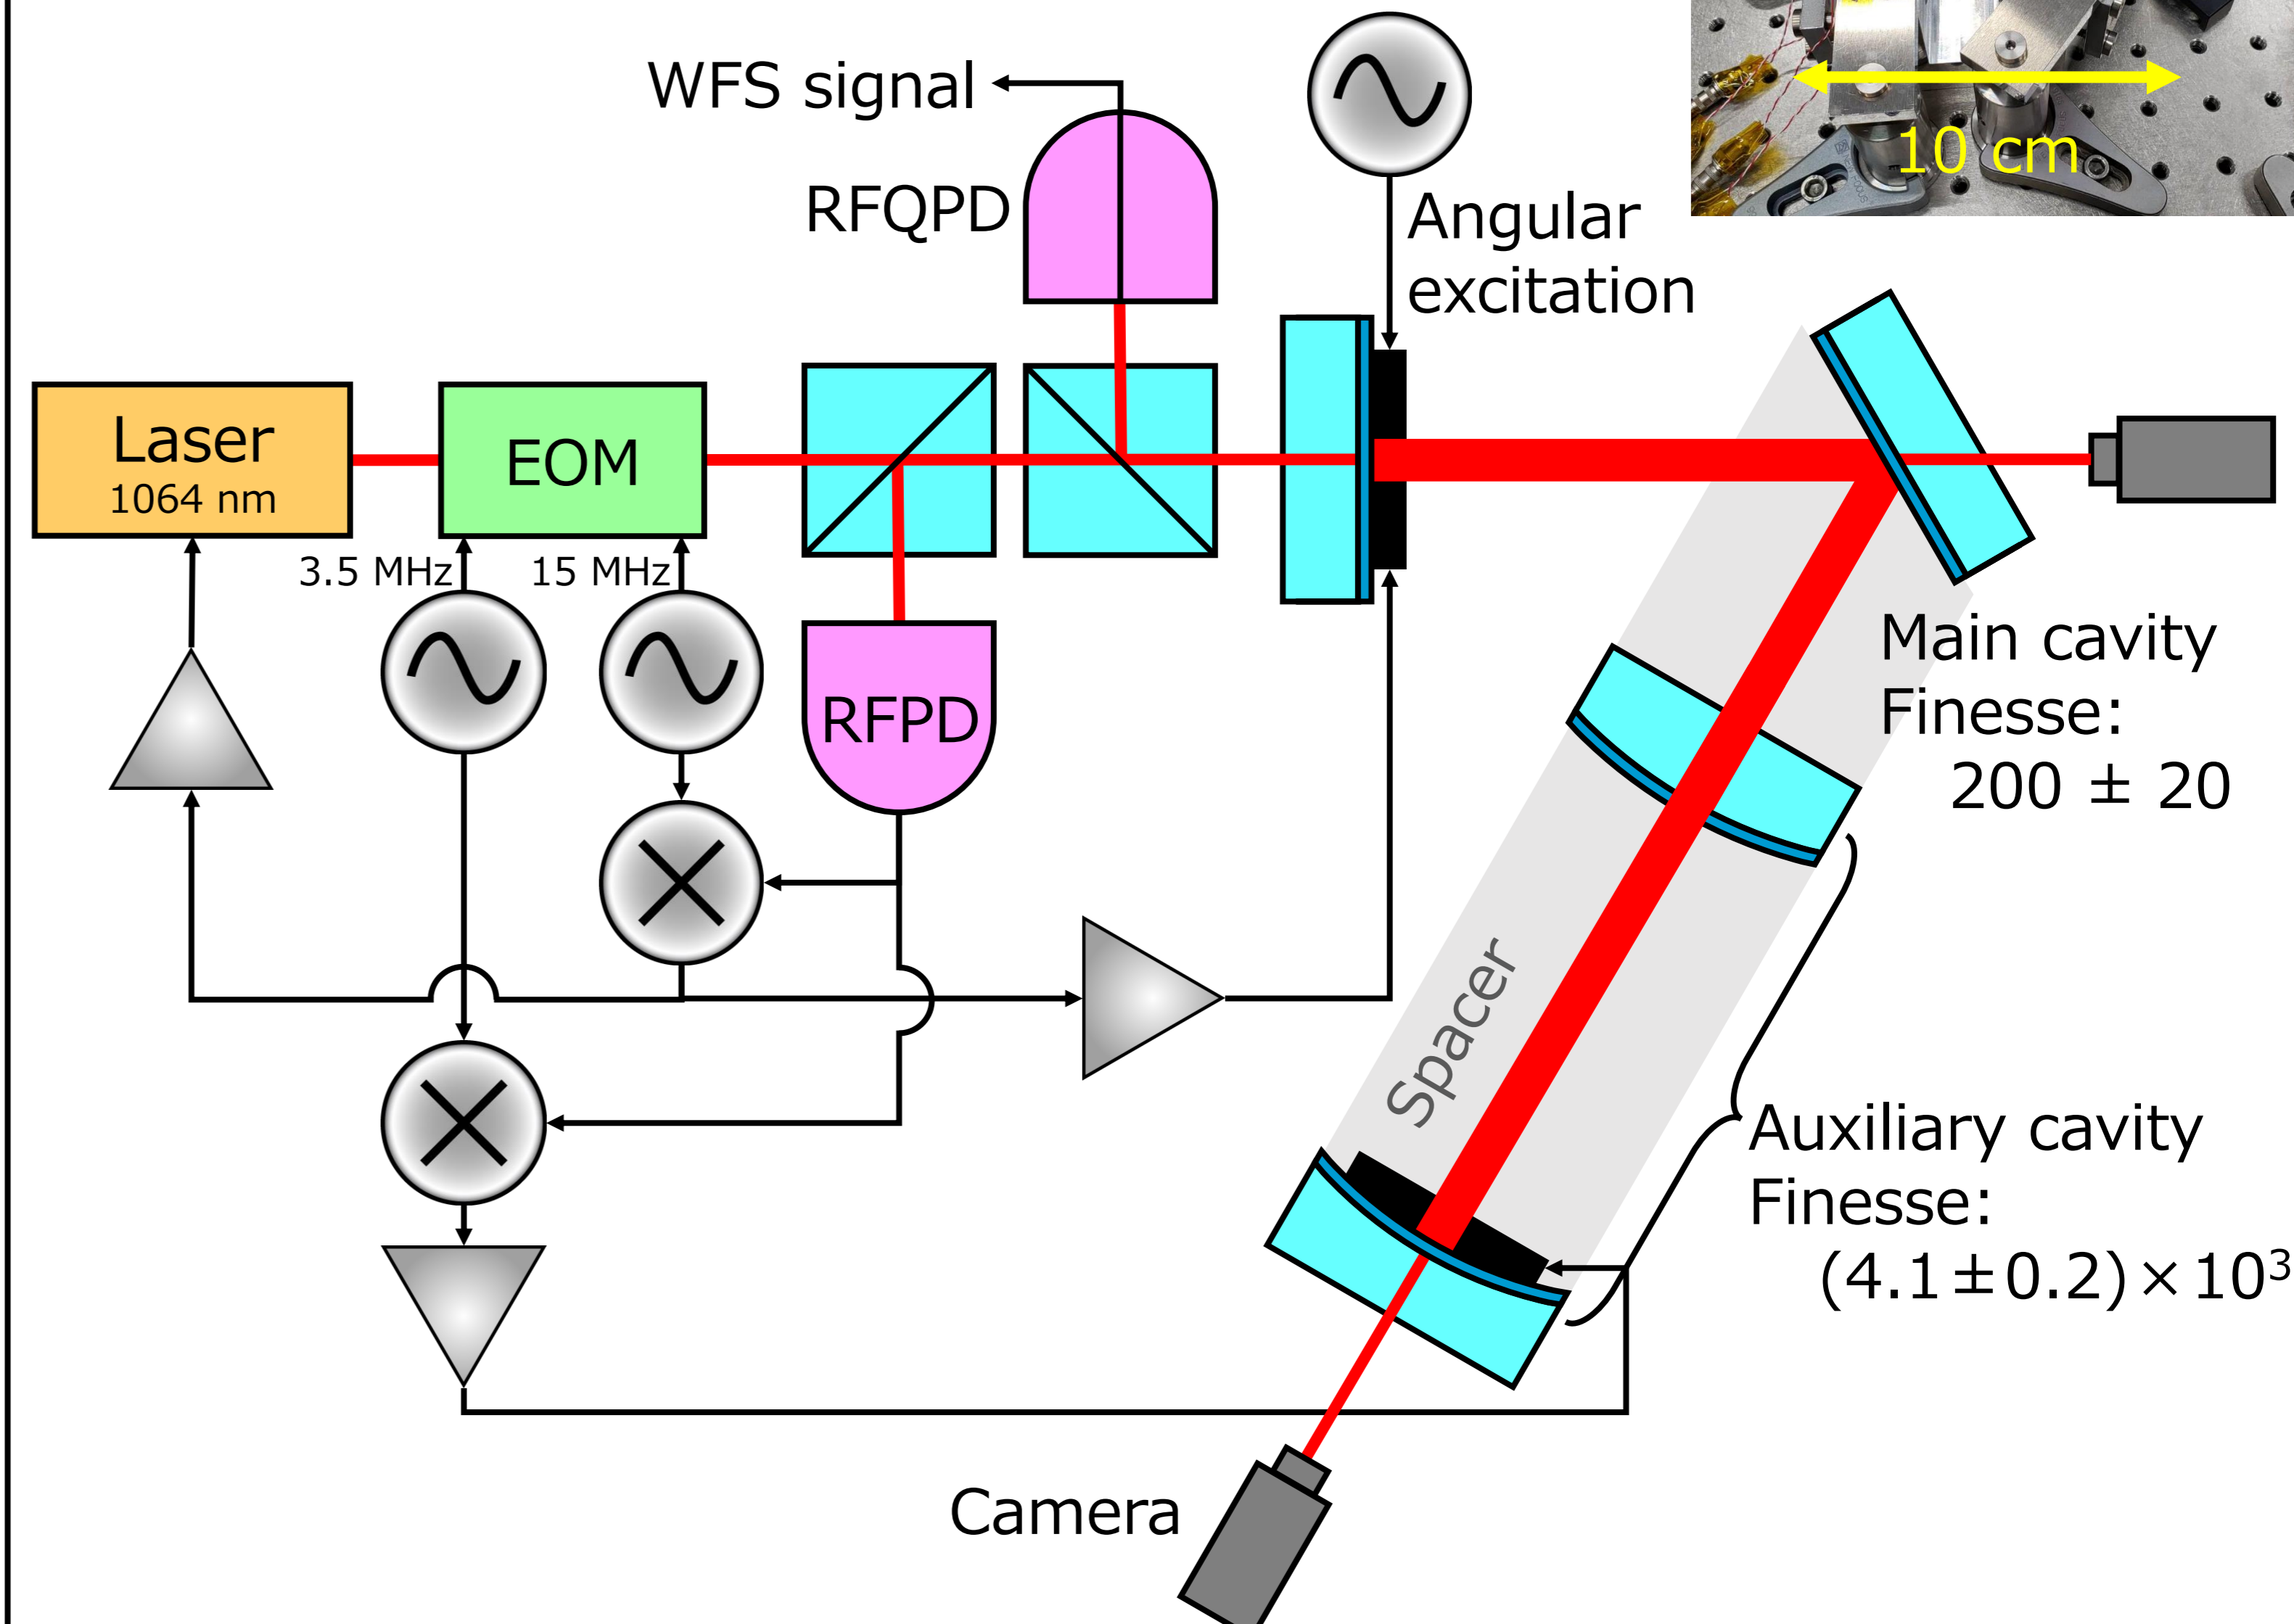

## 3. Experimental Setup of Coupled WFS

### Design of the coupled cavity

- Parameters are designed to allow Gouy phase compensation
- The main cavity is folded to monitor the transmitted light
- Mirrors are fixed to a spacer rigidly to stabilize the alignment

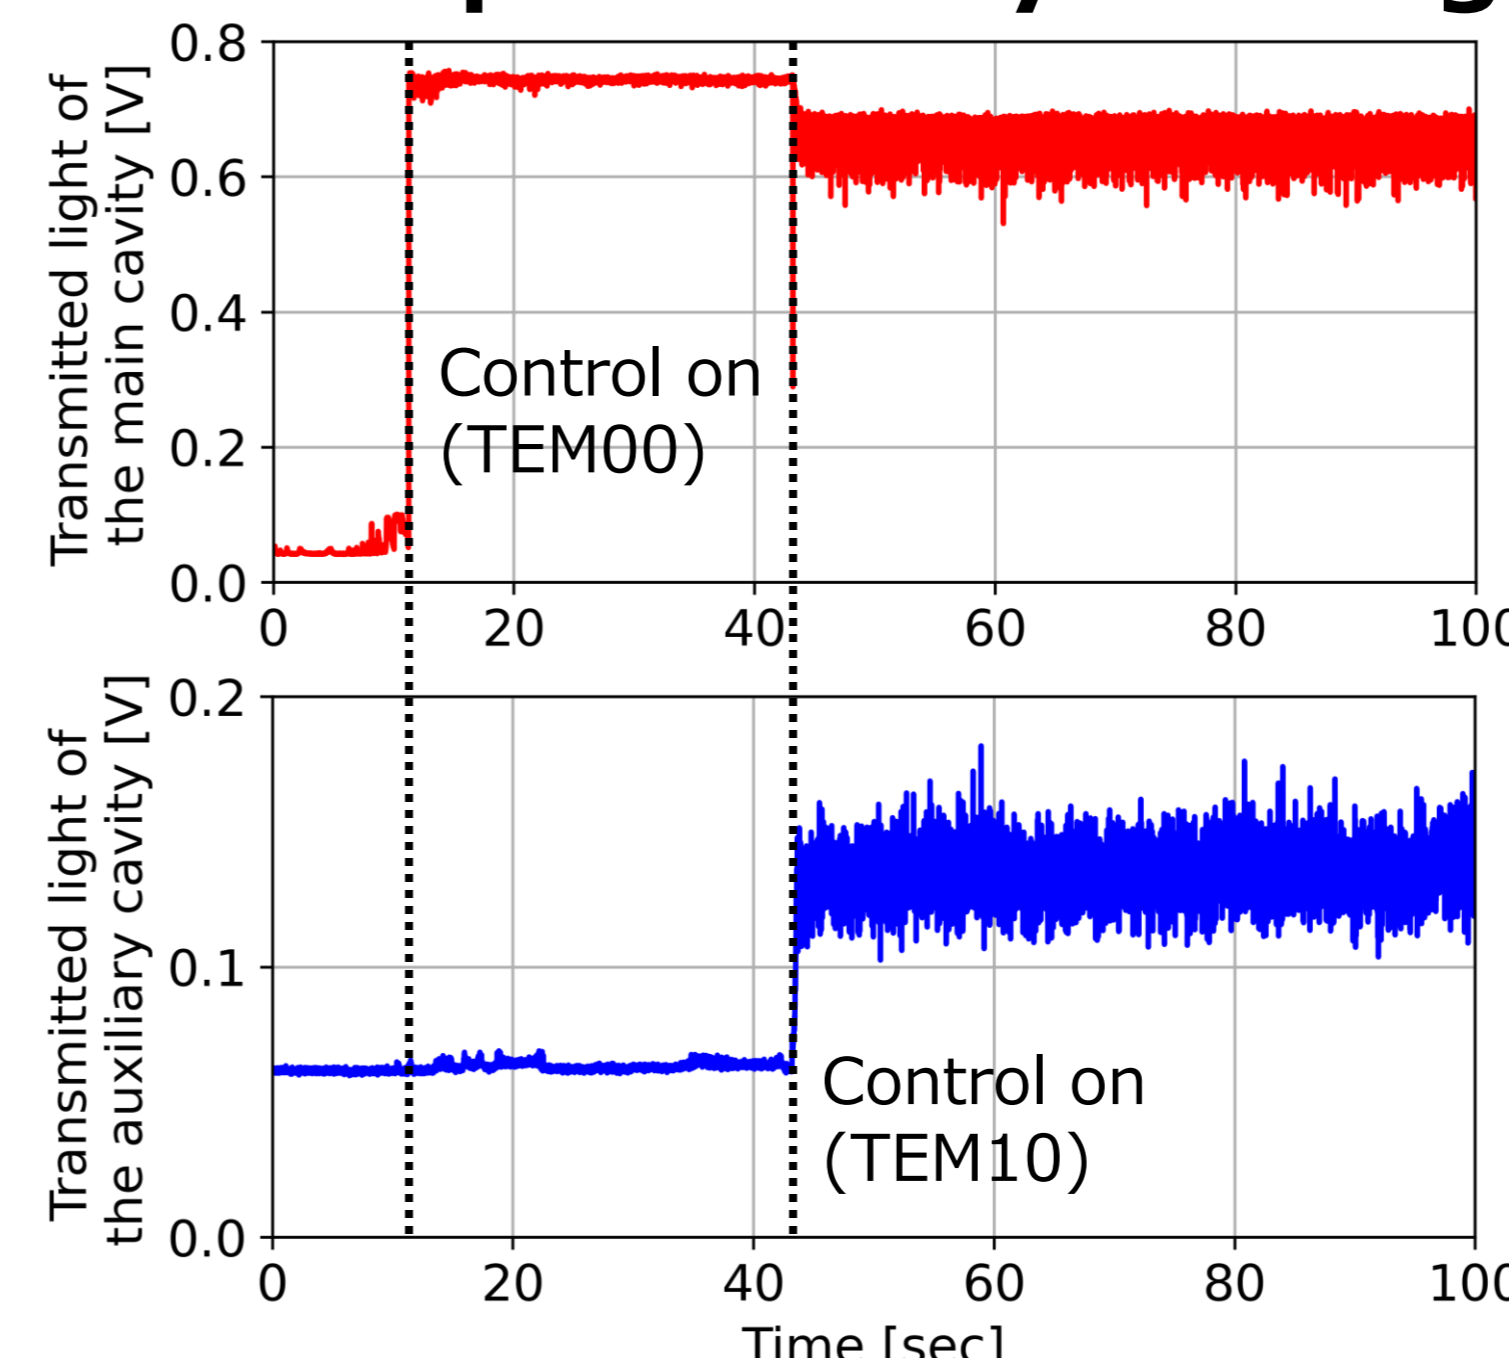

### Length control of the coupled cavity

- PDH technique with two modulation frequencies
- Hierarchical control for the main cavity

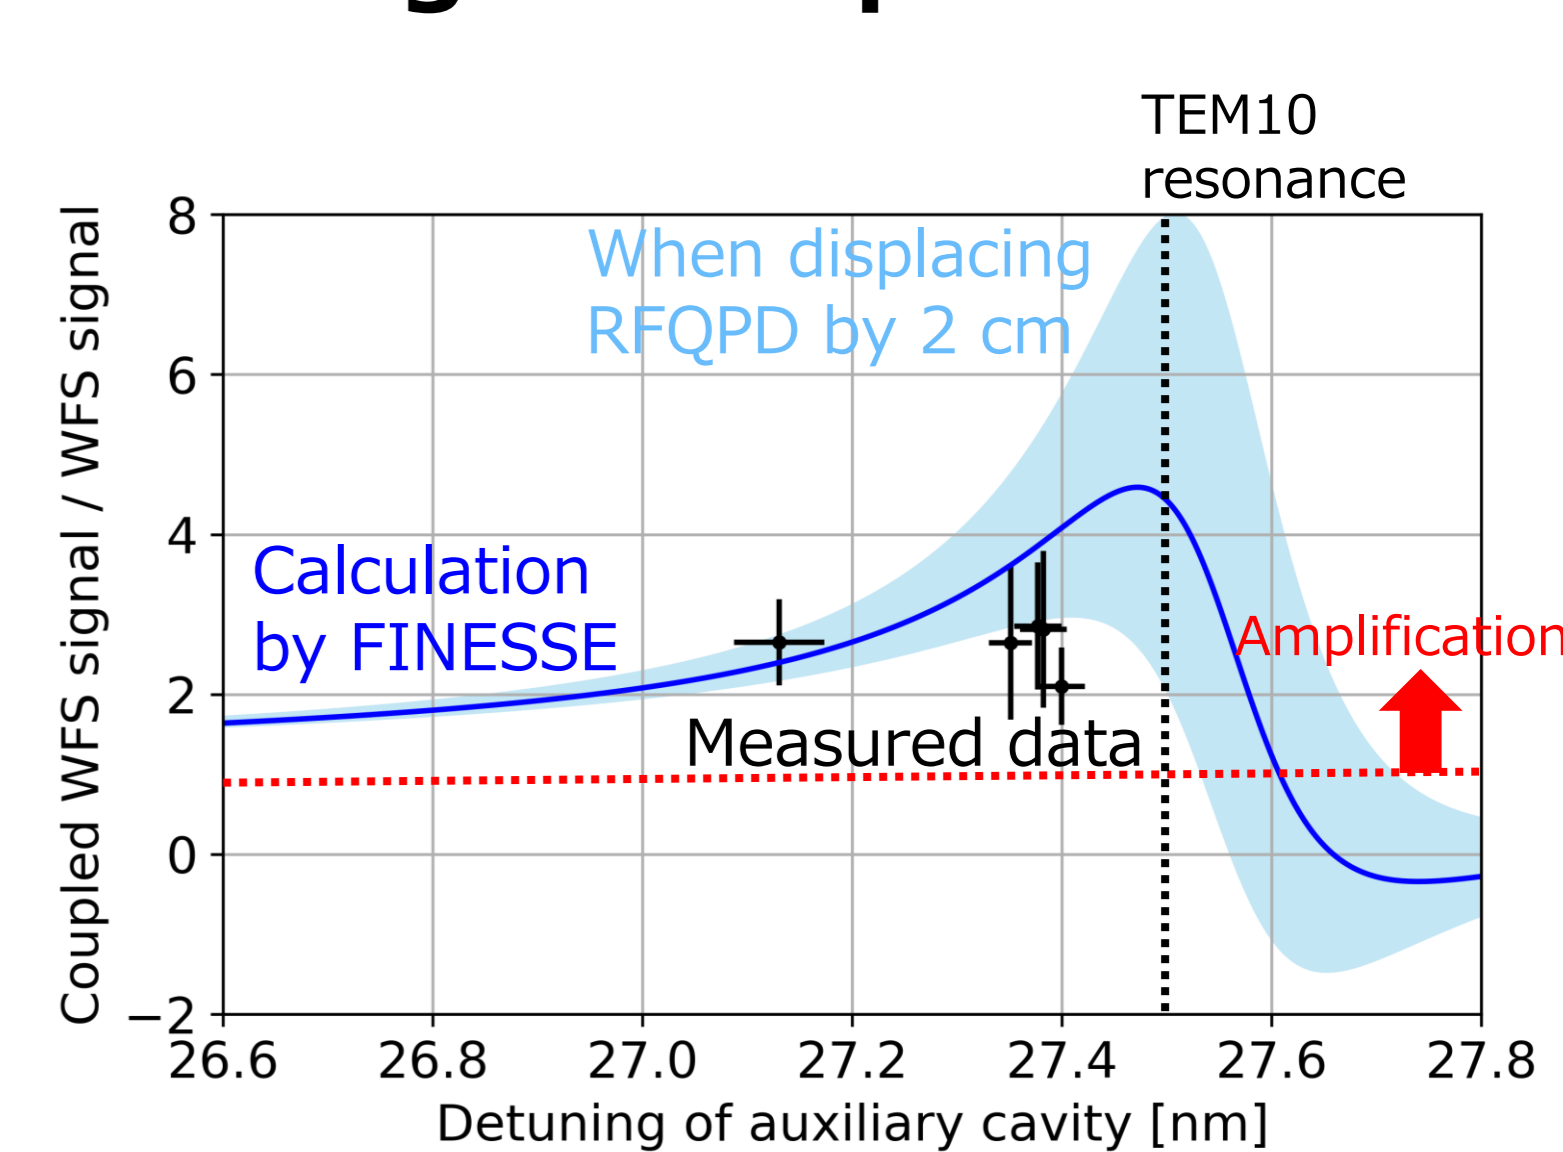

## 4. Results of Coupled WFS

### Coupled cavity locking

### Signal amplification

- Cavities were successfully locked TEM<sub>00</sub> and TEM<sub>10</sub> simultaneously
- Signal amplification was successfully demonstrated by three times

## 5. Summary & Future plans

- We are developing TOBA to detect GW in low frequency
- We propose Coupled WFS as an angular sensor for TOBA
- We demonstrated angular signal amplification and locking scheme of Coupled WFS
- We plan to suspend the test mass to stabilize the cavity lock
